# Galaxy Ecology

Many studies have investigated relation between various **galaxy properties** (morphology / SFR / colour) and **environment**

(e.g., Dressler 1980; Balogh et al. 2004; Goto et al. 2003; Hogg et al. 2004)

**Environment** estimated using **galaxy overdensity** (projected) to  $n^{\text{th}}$  nearest neighbour,  $\Sigma_n$  or using fixed, metric aperture,  $\Sigma_R$ .

Previous studies have found that:

- Fraction of early types **increases** with density
- There is a **characteristic density** ( $\sim$  group-scale) below which the environment dependence vanishes

**Danger:** Physical meaning of  $\Sigma_n$  and  $\Sigma_R$  depends on environment

Physically more meaningful to investigate **halo mass dependence** of galaxy properties. This requires **galaxy group catalogues**.

**Important:** Separate  $L$ -dependence from  $M$ -dependence

# Constructing Galaxy Groups Catalogues

Galaxy-Dark Matter connection can be studied more **directly** by measuring the occupation statistics of galaxy groups.

**Potential Problems:** interlopers, (in)completeness, mass estimates

We have developed a new, iterative group finder which uses an adaptive filter modeled after halo virial properties

Yang, Mo, vdB, Jing 2005, MNRAS, 356, 1293

- Calibrated & Optimized with **Mock Galaxy Redshift Surveys**
- Low **interloper** fraction ( $\lesssim 20\%$ ).
- High **completeness** of members ( $\gtrsim 90\%$ ).
- **Masses** estimated from group luminosities/stellar masses. More accurate than using **velocity dispersion** of members.
- Can also detect “groups” with single member
  - ▷ Large dynamic range ( $11.5 \lesssim \log[M/M_{\odot}] \lesssim 15$ ).

Group finder has been applied to both the **2dFGRS** (completed survey) and to the **SDSS** (NYU-VAGC DR2 + DR4; Blanton et al. 2005)

SDSS-DR2 data from NYU-VAGC (Blanton et al. 2005)  
 SSFRs from Kauffmann et al. (2003) and Brinchmann et al. (2004)

# Halo Mass Dependence

The fractions of **early** and **late** types depend strongly on halo mass.

At fixed halo mass, there is virtually **no luminosity dependence**.

The mass dependence is smooth: there is **no characteristic mass scale**

The **intermediate** type fraction is independent of luminosity and mass.

(Weinmann, vdB, Yang & Mo, 2006)

- SAM matches **global statistics** of SDSS
- LF, bimodal color distribution, and overall blue fraction
- But what about statistics as function of halo mass?

# Constraining Star Formation Truncation

To allow for fair comparison, we run our Group Finder over **SAM**.

Weinmann et al. (astro-ph/0606458)

Satellites: red fraction too large:  $\triangleright$  **strangulation** too efficient

Centrals:  $f_{\text{blue}}(L|M)$  wrong:  $\triangleright$  Problem with **AGN feedback** or **dust**

$f_{\text{blue}}(L, M)$  useful to constrain SF truncation mechanism

# Stochasticity and Stacking

To measure **satellite kinematics** or the **weak lensing** shear around galaxies, one needs to stack the signal of many galaxies.

Typically one stacks (central) galaxies in a narrow luminosity bin.

Unless  $P(M|L_{\text{cen}})$  is very narrow, this means stacking haloes of different masses, and signal does not reflect  $\langle M \rangle(L_{\text{cen}})$ .

Proper interpretation of **satellite kinematics** and **galaxy-galaxy lensing** requires knowledge of  $\sigma_{\log M}$ .

How can we constrain the scatter in  $P(M|L_{\text{cen}})$ ?

- Use 'predictions' from **semi-analytical models** for galaxy formation
- Compute from **CLF**:  $P(M|L_{\text{cen}}) = \frac{\Phi_c(L|M) n(M)}{\Phi_c(L)}$  (*Bayes Theorem*)
- Use **satellite kinematics**; host-weighting vs. satellite weighting

● The Scatter in  
 $P(M|L_{\text{cen}})$

Conclusions

Extra Material

# Satellite Kinematics

Select **centrals** and **satellites** and determine  $\sigma_{\text{sat}}(L_{\text{cen}})$ , describing the width of  $P(\Delta V)$  with  $\Delta V = V_{\text{sat}} - V_{\text{cen}}$  (More, vdB, et al. 2007, in prep.)

$$\langle \sigma_{\text{sat}} \rangle (L_{\text{cen}}) = \frac{\int P(M|L_{\text{cen}}) \langle N_{\text{sat}} \rangle_M^p \langle \sigma_{\text{sat}} \rangle_M dM}{\int P(M|L_{\text{cen}}) \langle N_{\text{sat}} \rangle_M^p dM}$$

- $p = 1$ : **satellite-weighted mean**  $\langle \sigma_{\text{sat}} \rangle_{\text{sw}}$
- $p = 0$ : **host-weighted mean**  $\langle \sigma_{\text{sat}} \rangle_{\text{hw}}$

**Unless**  $P(M|L_{\text{cen}}) = \delta(M - \langle M \rangle)$  **one has that**  $\langle \sigma_{\text{sat}} \rangle_{\text{sw}} > \langle \sigma_{\text{sat}} \rangle_{\text{hw}}$

**Both**  $\langle \sigma_{\text{sat}} \rangle_{\text{sw}}$  **and**  $\langle \sigma_{\text{sat}} \rangle_{\text{hw}}$  **can be determined from data.**

• The Scatter in  $P(M|L_{\text{cen}})$

Conclusions

Extra Material

# The Scatter in $P(M|L_{cen})$

Assuming that  $P(M|L_{cen})$  is a log-normal, the combination of  $\langle \sigma_{sat} \rangle_{sw}$  and  $\langle \sigma_{sat} \rangle_{hw}$  allows one to compute both  $\langle M \rangle$  and  $\sigma_{\log M}$  as function of  $L_{cen}$ .

(More, vdB et al. 2007, in prep.)

All methods agree that scatter in  $P(M|L_{cen})$  increases with  $L_{cen}$

- Modern redshift surveys allow the construction of large and well-defined **group catalogues**.
- The ecology of **galaxies** yields useful constraints on physics of galaxy formation.
- The ecology of **AGN** agrees with a “cold-mode” to “hot-mode” transition at  $M \simeq 10^{12} - 10^{13} h^{-1} M_{\odot}$
- Satellite kinematics can be used to probe and quantify the **stochasticity** in galaxy formation.
- Scatter in  $P(M|L_{\text{cen}})$  increases strongly with increasing  $L_{\text{cen}}$
