Problem 1: The Venturi Meter

The venturi meter is used to measure the flow speed in a pipe. An example is shown in Fig. 1, where the venturi meter (indicated by the dashed lines) is placed in a pipe of diameter $A_1$. The venturi meter itself consists of a pipe of diameter $A_2$, as indicated. The pipe transports an incompressible fluid of density $\rho$ with a flow velocity $u_1$ (this is the quantity to be measured). The flow velocity in the narrow pipe is $u_2$. The main and narrow pipes are connected via a U-shaped pipe that is filled with a fluid of density $\tilde{\rho} > \rho$. The quantity to be measured is $h$, the difference in the heights of the columns of the dense fluid. Throughout you may assume that the fluid flowing through the venturi meter is ideal.

a) [3 points] Show that, for an ideal fluid, the specific enthalpy $h \equiv \varepsilon + P/\rho$ takes on the following form:

$$h = \frac{\gamma}{\gamma - 1} \frac{P}{\rho}$$

with $\gamma$ the adiabatic index.

b) [5 points] Assume that the venturi meter of Fig. 1 is located in the Earth’s gravitational field, with the direction of gravitational acceleration perpendicular to the flow direction. Express the pressure difference at points 1 and 2 in terms of $u_1$, $u_2$, and $\rho$. You can assume that the flow is laminar.

c) [5 points] Derive an expression for $u_1$ as function of $h$, the densities $\rho$ and $\tilde{\rho}$, and the areas $A_1$ and $A_2$. 

1
Problem 2: Vorticity in a thin disk [8 points]
Consider an infinitesimally thin disk of fluid in rotation around the disk’s (vertical) symmetry axis. It is given that the flow is symmetric around the same symmetry axis, and that the circulation around any curve $C$ on the disk is zero, as long as the curve does not enclose the symmetry point of the disk, $R = 0$. Derive an expression for the velocity field $\vec{u}(\vec{x})$, i.e., what are the various components of $\vec{u}$ as function of location in the disk? Clearly explain your steps in this derivation.
Problem 3: Purely Radial Stellar Oscillations
Consider a spherical, barotropic star for which $P = K\rho^\gamma$. The goal is to derive conditions for $\gamma$ under which the star is stable to radial oscillations. Suppose the star is uniformly expanded from an initial equilibrium configuration such that the position of a fluid element (or mass shell) changes from $r_0$ to $r_0(1 + \delta)$. Throughout we shall assume that $\delta$ is small, such that we can use perturbation theory. From the Euler equation (i.e., ignoring viscosity) we can write down the acceleration of a fluid element at a distance $r$ from the center of the star as

$$\frac{dv}{dt} = -\frac{1}{\rho} \frac{dP}{dr} - \frac{GM(r)}{r^2}$$

where $v$ is the radial component of the velocity (we are considering purely radial motions here) and $M(r)$ is the mass enclosed within radius $r$.

a) [6 points] Use Taylor series expansion to show that, to linear order, the density of the perturbed mass shell obeys $\rho = \rho_0(1 - 3\delta)$.

b) [5 points] Using the same strategy, given a similar expression for $P$ in terms of $P_0$, $\delta$, and $\gamma$.

c) [6 points] Substitute the expressions for $r$, $\rho$ and $P$ in the expression for the radial acceleration, keeping only terms up to linear order, and derive for what values of $\gamma$ the star will be stable to radial oscillations. Note: assume that the initial configuration was one of equilibrium, so that

$$-\frac{1}{\rho_0} \frac{dP_0}{dr_0} - \frac{GM(r_0)}{r_0^2} = 0$$

and explain your answer!
Problem 4: Bondi Accretion

Consider a homogeneous, ideal fluid of density $\rho_\infty$ and with sound speed $c_\infty$. If a spherical body of mass $M$ (i.e., a star or a black hole) is placed in this medium (at $\vec{r} = 0$), the gravity due to $M$ will induce a flow towards it. Consequently, the mass $M$ will start to accrete matter from its ambient medium. In what follows we assume that the flow that develops is steady and isothermal (i.e., it is assumed that the heating associated with the compression of the fluid is radiated away, such that the temperature of the accreting fluid remains constant).

a) [4 points] Show that the pressure potential $h = \int dP/\rho$ for the isothermal accretion flow is equal to $c_\infty^2 \ln(\rho/\rho_\infty)$, where $\rho$ is the density in the flow at the radius where $h$ is evaluated.

b) [4 points] Use the continuity equation to show that $r^2 \rho(r) u(r)$ is independent of the distance $r$ from $M$, and show that this implies that

$$\frac{d \ln \rho}{dr} = -\frac{2}{r} - \frac{d \ln u}{dr}$$

Here $u(r) = |\vec{u}(\vec{r})|$ is the velocity of the accretion flow.

The above implies that the mass accretion rate $\dot{M} = 4\pi r^2 \rho u$ is also constant with radius (and, under the assumption of an infinite supply of ambient medium) and time.

c) [5 points] Starting from the momentum equation for the accretion flow in Eulerian form, show that

$$(u^2 - c_s^2) \frac{d \ln u}{dr} = \frac{2c_s^2}{r} \left[ 1 - \frac{GM}{2c_s^2 r} \right]$$

Hint: Use the results derived under b).

d) [3 points] The radius at which the fluid flow transits from being subsonic to being supersonic is called the sonic radius, $r_s$. Derive an expression for $r_s$ in terms of $M$ and $c_s$. 

4
e) [4 points] Use the fact that in a steady, barotropic flow Bernoulli’s constant is conserved along particle paths to show that

\[ \rho_s \equiv \rho(r_s) = \rho_\infty e^{1.5} \]

Hint: use that \( \lim_{r \to \infty} u = 0 \).

f) [2 points] Write down an expression for the accretion rate onto \( M \) as a function of \( \rho_\infty, c_\infty \) and \( M \).

g) [6 points] The center of the Milky Way harbors a black hole of mass \( M \approx 10^6 M_\odot \). Assuming the (infinite reservoir of) ambient gas has a number density \( n = 1 \text{ cm}^{-3} \), a mean molecular weight \( \mu = 1 \) (i.e., the mean particle mass is equal to the mass of a proton), and a temperature \( T = 10^7 \text{K} \), how long does it take for the black hole to double its mass due to steady, isothermal Bondi accretion of gas from its ambient medium? Show your derivation in detail and express your answer in units of the Hubble time \( t_H \approx 10^{10} \text{ year} \), which is roughly the age of the Universe.
