Lecture 13: The Halo Model & Halo Occupation Statistics

FRANK VAN DEN BOSCH YALE UNIVERSITY, FALL 2022

## Halo Model & Halo Occupation Statistics

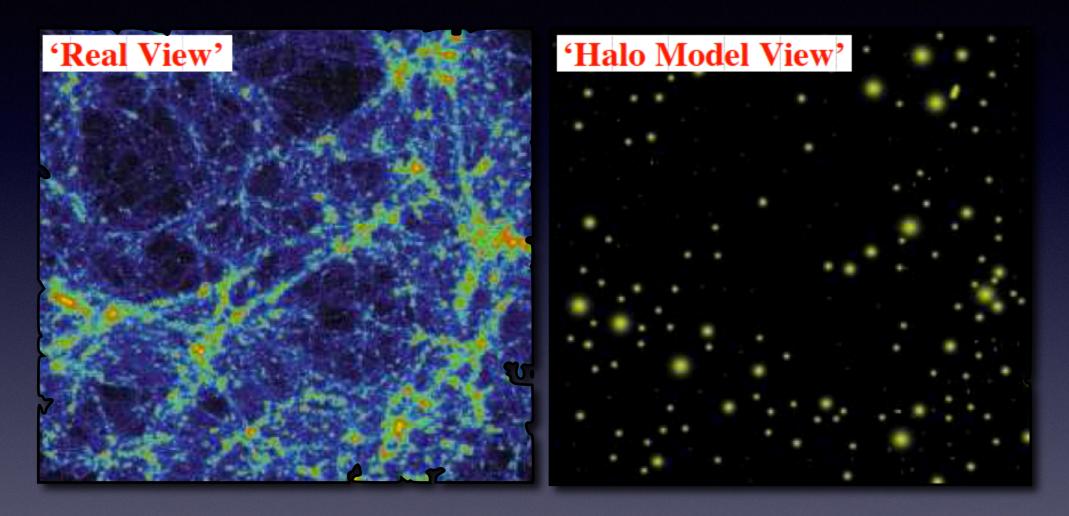

In this lecture we discuss the "halo model", an analytical model to describe the (dark matter) mass distribution on small, non-linear scales. We also introduce the concept of halo occupation statistics and discuss how data can constrain these. We end with some discussion on the galaxy-dark matter connection

#### Topics that will be covered include:

- The Halo Model
- 1-halo vs 2-halo terms
- Halo Occupation Models
- Halo Exclusion
- Conditional Luminosity Function
- Poisson statistics
- Galaxy-Dark Matter Connection

The Halo model is an analytical model that describes dark matter density distribution in terms of its halo building blocks, under ansatz that all dark matter is partitioned over haloes.

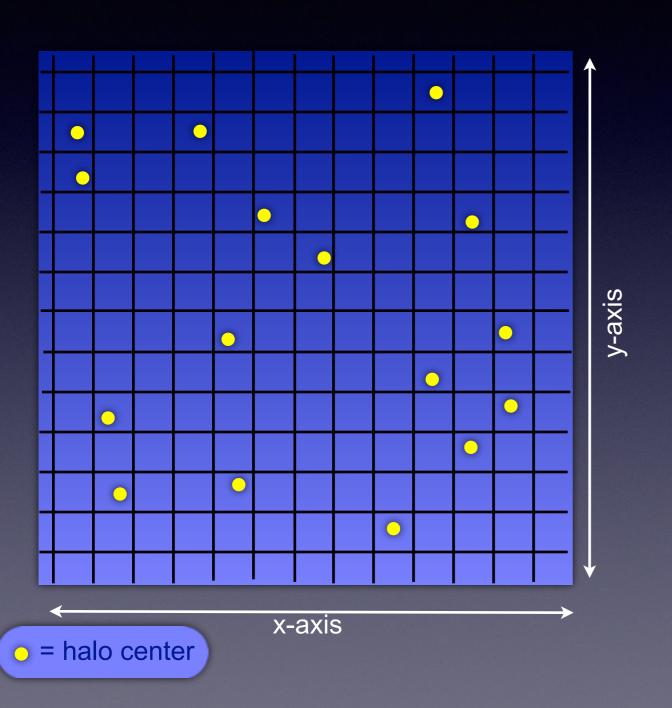

Throughout we assume that all dark matter haloes are spherical, and have a density distribution that only depends on halo mass:

$$\rho(r|M) = M u(r|M)$$

Here u(r|M) is the normalized density profile:

$$\int \mathrm{d}^3 \vec{x} \, u(\vec{x}|M) = 1$$

Imagine space divided into many small volumes,  $\Delta V_i$ , which are so small that none of them contain more than one halo center.

Let  $\mathcal{N}_i$  be the occupation number of dark matter haloes in cell i

Then we have that  $\mathcal{N}_i = 0, 1$  and therefore  $\mathcal{N}_i = \mathcal{N}_i^2 = \mathcal{N}_i^3 = 0$ 

This allows us to write the matter density field as a summation:

$$\rho(\vec{x}) = \sum_{i} \mathcal{N}_{i} M_{i} u(\vec{x} - \vec{x}_{i}|M_{i})$$

$$\rho(\vec{x}) = \sum_{i} \mathcal{N}_{i} M_{i} u(\vec{x} - \vec{x}_{i}|M_{i})$$

$$\overline{\rho} = \int \rho(\vec{x}) \, \mathrm{d}^3 \vec{x} = \left\langle \rho(\vec{x}) \right\rangle = \left\langle \sum_i \mathcal{N}_i \, M_i \, u(\vec{x} - \vec{x}_i | M_i) \right\rangle$$
 ergodicity 
$$= \sum_i \left\langle \mathcal{N}_i \, M_i \, u(\vec{x} - \vec{x}_i | M_i) \right\rangle \quad \text{halo mass function}$$
 
$$= \sum_i \int \mathrm{d}M \, M \, n(M) \Delta V_i \, u(\vec{x} - \vec{x}_i | M)$$
 
$$= \int \mathrm{d}M \, M \, n(M) \int \mathrm{d}^3 \vec{y} \, u(\vec{x} - \vec{y} | M)$$
 
$$= \int \mathrm{d}M \, M \, n(M)$$

Q.E.D.

$$\rho(\vec{x}) = \sum_{i} \mathcal{N}_{i} M_{i} u(\vec{x} - \vec{x}_{i}|M_{i})$$

Now that we can write the density field in terms of the halo building blocks, let's focus on two-point statistics:  $\xi_{\rm mm}(r) \equiv \langle \delta(\vec{x}) \, \delta(\vec{x} + \vec{r}) \rangle = \frac{1}{\bar{\rho}^2} \langle \rho(\vec{x}) \, \rho(\vec{x} + \vec{r}) \rangle - 1$ 

$$\langle \rho(\vec{x}) \rho(\vec{x} + \vec{r}) \rangle = \left\langle \sum_{i} \mathcal{N}_{i} M_{i} u(\vec{x}_{1} - \vec{x}_{i}|M_{i}) \cdot \sum_{j} \mathcal{N}_{j} M_{j} u(\vec{x}_{2} - \vec{x}_{j}|M_{j}) \right\rangle$$

$$\vec{x}_2 = \vec{x}_1 + \vec{r}$$

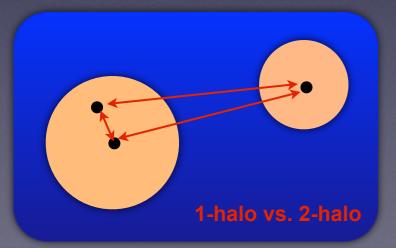

$$= \sum_{i} \sum_{j} \langle \mathcal{N}_{i} \mathcal{N}_{j} M_{i} M_{j} u(\vec{x}_{1} - \vec{x}_{i} | M_{i}) u(\vec{x}_{2} - \vec{x}_{j} | M_{j}) \rangle$$

We split this in two parts: the 1-halo term (i = j), and the 2-halo term  $(i \neq j)$ 

For the 1-halo term we obtain:

$$\mathcal{N}_i^2 = \mathcal{N}_i$$

$$\langle \rho(\vec{x}) \, \rho(\vec{x} + \vec{r}) \rangle_{1h} = \sum_{i} \langle \mathcal{N}_i \, M_i^2 \, u(\vec{x}_1 - \vec{x}_i | M_i) u(\vec{x}_2 - \vec{x}_i | M_i) \rangle$$

$$= \sum_{i} \int dM M^{2} n(M) \Delta V_{i} u(\vec{x}_{1} - \vec{x}_{i}|M) u(\vec{x}_{2} - \vec{x}_{i}|M)$$

$$= \int dM M^2 n(M) \int d^3 \vec{y} u(\vec{x}_1 - \vec{y}|M) u(\vec{x}_2 - \vec{y}|M)$$

convolution integral

$$\rho(\vec{x}) = \sum_{i} \mathcal{N}_{i} M_{i} u(\vec{x} - \vec{x}_{i}|M_{i})$$

For the 2-halo term we obtain:

$$\langle \rho(\vec{x}) \rho(\vec{x} + \vec{r}) \rangle_{2h} = \sum_{i} \sum_{j \neq i} \langle \mathcal{N}_{i} \mathcal{N}_{j} M_{i} M_{j} u(\vec{x}_{1} - \vec{x}_{i} | M_{i}) u(\vec{x}_{2} - \vec{x}_{j} | M_{j}) \rangle$$

$$\stackrel{?}{\neq} \sum_{i} \sum_{j \neq i} \int dM_{1} M_{1} n(M_{1}) \int dM_{2} M_{2} n(M_{2}) \Delta V_{i} \Delta V_{j} \times u(\vec{x}_{1} - \vec{x}_{i} | M_{1}) u(\vec{x}_{2} - \vec{x}_{j} | M_{2}) = \overline{\rho}^{2}$$

NO: dark matter haloes themselves are clustered, i.e., have a non-zero two point correlation function. This needs to be taken into account.

Clustering of dark matter haloes is characterized by halo-halo correlation function:

$$\xi_{\rm hh}(r|M_1,M_2) = b(M_1) \, b(M_2) \, \xi_{\rm mm}^{\rm lin}(r)$$

Here b(M) is the halo bias function. Note: the above description of the halo-halo correlation function is only valid on large (linear) scales! On small scales non-linearities and halo exclusion become important (see below).

 $\rho(\vec{x}) = \sum_{i} \mathcal{N}_{i} M_{i} u(\vec{x} - \vec{x}_{i}|M_{i})$ 

For the 2-halo term we obtain:

$$\begin{split} \langle \rho(\vec{x}) \, \rho(\vec{x} + \vec{r}) \rangle_{2\mathrm{h}} &= \sum_{i} \sum_{j \neq i} \langle \mathcal{N}_{i} \, \mathcal{N}_{j} \, M_{i} \, M_{j} \, u(\vec{x}_{1} - \vec{x}_{i} | M_{i}) \, u(\vec{x}_{2} - \vec{x}_{j} | M_{j}) \rangle \\ &= \sum_{i} \sum_{j \neq i} \int \mathrm{d}M_{1} \, M_{1} \, n(M_{1}) \, \int \mathrm{d}M_{2} \, M_{2} \, n(M_{2}) \, \Delta V_{i} \, \Delta V_{j} \, \times \\ & \left[ 1 + \xi_{\mathrm{hh}} (\vec{x}_{i} - \vec{x}_{j} | M_{1}, M_{2}) \right] u(\vec{x}_{1} - \vec{x}_{i} | M_{1}) \, u(\vec{x}_{2} - \vec{x}_{j} | M_{2}) \\ &= \quad \vec{\rho}^{2} + \int \mathrm{d}M_{1} \, M_{1} \, n(M_{1}) \, \int \mathrm{d}M_{2} \, M_{2} \, n(M_{2}) \, \times \\ & \int \mathrm{d}^{3} \vec{y}_{1} \int \mathrm{d}^{3} \vec{y}_{2} \, u(\vec{x}_{1} - \vec{y}_{1} | M_{1}) \, u(\vec{x}_{2} - \vec{y}_{2} | M_{2}) \, \xi_{\mathrm{hh}} (\vec{y}_{1} - \vec{y}_{2} | M_{1}, M_{2}) \\ &= \quad \vec{\rho}^{2} + \int \mathrm{d}M_{1} \, M_{1} \, b(M_{1}) \, n(M_{1}) \int \mathrm{d}M_{2} \, M_{2} \, b(M_{2}) \, n(M_{2}) \, \times \\ & \int \mathrm{d}^{3} \vec{y}_{1} \int \mathrm{d}^{3} \vec{y}_{2} \, u(\vec{x}_{1} - \vec{y}_{1} | M_{1}) \, u(\vec{x}_{2} - \vec{y}_{2} | M_{2}) \, \xi_{\mathrm{min}}^{\mathrm{lin}} (\vec{y}_{1} - \vec{y}_{2}) \\ & \text{convolution integral} \end{split}$$

#### The Halo Model: Summary

$$\xi(r) = \xi^{1h}(r) + \xi^{2h}(r)$$

$$\xi^{1h}(r) = \frac{1}{\overline{\rho}^2} \int dM M^2 n(M) \int d^3 \vec{y} \, u(\vec{x} - \vec{y}|M) u(\vec{x} + \vec{r} - \vec{y}|M)$$

$$\xi^{2h}(r) = \frac{1}{\overline{\rho}^2} \int dM_1 \, M_1 \, b(M_1) \, n(M_1) \int dM_2 \, M_2 \, b(M_2) \, n(M_2) \times$$

$$\int d^3 \vec{y}_1 \int d^3 \vec{y}_2 u(\vec{x} - \vec{y}_1|M_1) \, u(\vec{x} + \vec{r} - \vec{y}_2|M_2) \, \xi_{\text{mm}}^{\text{lin}}(\vec{y}_1 - \vec{y}_2)$$

Halo Model Ingredients:

- the halo density profiles ho(r|M) = Mu(r|M)
- the halo mass function n(M)
- the halo bias function b(M)
- the linear correlation function of matter

 $\xi_{
m mm}^{
m lin}(r)$ 

All of these are (reasonably) well calibrated against numerical simulations.

#### The Halo Model in Fourier Space

$$P(k) = P^{1h}(k) + P^{2h}(k)$$

$$P^{1h}(k) = \frac{1}{\overline{\rho}^2} \int dM M^2 n(M) |\tilde{u}(k|M)|^2$$

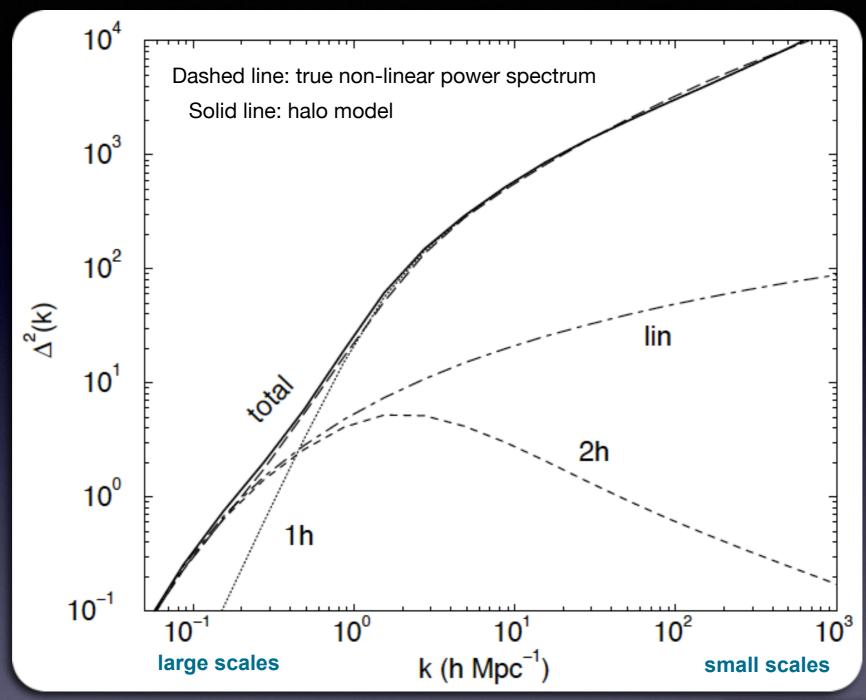

$$P^{2h}(k) = P^{lin}(k) \left[ \frac{1}{\overline{\rho}} \int dM M b(M) n(M) \tilde{u}(k|M) \right]^2$$

$$P^{\text{lin}}(k) = P_{i}(k) T^{2}(k) = k^{n_{s}} T^{2}(k)$$

$$\tilde{u}(\vec{k}|M) = \int u(\vec{x}|M) e^{-i\vec{k}\cdot\vec{x}} d^{3}\vec{x} = 4\pi \int_{0}^{\infty} u(r|M) \frac{\sin kr}{kr} r^{2} dr$$

Since convolutions in real-space become multiplications in Fourier space, the halo model expression for the power spectrum is much easier. Therefore, in practice, one computes P(k) and then uses Fourier transformation to obtain two-point correlation function  $\xi(r)$ 

## The Halo Model in Fourier Space

Source: Cooray & Sheth (2002)

$$\Delta^2(k) = \frac{1}{2\pi^2} k^3 P(k)$$

Dimensionless power spectrum

# The Halo Model: complications

$$P^{1h}(k) = \frac{1}{\bar{\rho}^2} \int dM M^2 n(M) |\tilde{u}(k|M)|^2$$

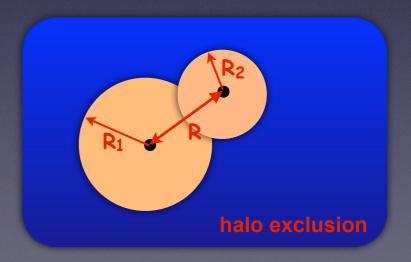

$$P^{2h}(k) = P^{\text{lin}}(k) \left[ \frac{1}{\bar{\rho}} \int dM M b(M) n(M) \tilde{u}(k|M) \right]^2$$

However, this is ONLY true under the simplifying assumption that

$$\xi_{\rm hh}(r|M_1,M_2) = b(M_1) b(M_2) \xi_{\rm mm}^{\rm lin}(r)$$

In reality, on small scales, in the (quasi)-linear regime, this description of the halo-halo correlation function becomes inadequate for two reasons:

- $\xi_{\rm mm}^{\rm lin}(r)$  is no longer adequate
- halo exclusion

Properly accounting for this is complicated

(if interested, see vdBosch+13)

## The Galaxy Power Spectrum

$$P^{1h}(k) = \frac{1}{\overline{\rho}^2} \int dM M^2 n(M) |\tilde{u}(k|M)|^2$$

$$P^{2h}(k) = P^{lin}(k) \left[ \frac{1}{\overline{\rho}} \int dM M b(M) n(M) \tilde{u}(k|M) \right]^2$$

The above equations describe the halo model predictions for the matter power spectrum

The same formalism can also be used to compute the galaxy power spectrum:

simply replace:

$$\frac{M}{\bar{\rho}} \longrightarrow \frac{\langle N \rangle_M}{\bar{n}_g}$$

$$\frac{M^2}{\bar{\rho}^2} \longrightarrow \frac{\langle N(N-1) \rangle_M}{\bar{n}_g^2}$$

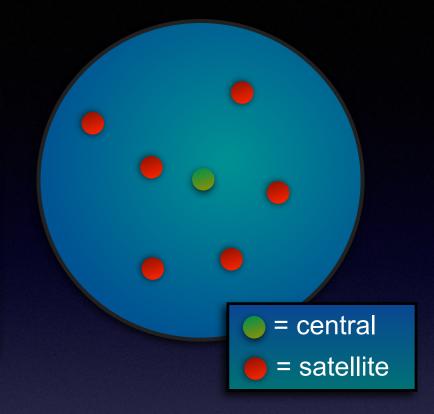

$$\tilde{u}(k|M) \longrightarrow \tilde{u}_g(k|M)$$

Here  $\langle N \rangle_M$  describes average number of galaxies (with certain properties) that reside in a halo of mass M,  $\bar{n}_{\rm g}$  is the average number density of those galaxies, and  $u_{\rm g}(r|M)$  is the normalized, radial number density distribution of galaxies in haloes of mass M.

When describing halo occupation statistics, it is important to treat central and satellite galaxies separately.

Central Galaxies: those galaxies that reside at the center of their dark matter (host) halo

Satellite Galaxies: those galaxies that reside at the center of a dark matter sub-halo, and are orbitting inside a larger host halo.

#### **Central Galaxies**

$$\langle N_{\rm c}\rangle_{M} = \sum_{N_{\rm c}=0}^{1} N_{\rm c} P(N_{\rm c}|M) = P(N_{\rm c}=1|M)$$
$$\langle N_{\rm c}^{2}\rangle_{M} = \sum_{N_{\rm c}=0}^{1} N_{\rm c}^{2} P(N_{\rm c}|M) = P(N_{\rm c}=1|M) = \langle N_{\rm c}\rangle_{M}$$
$$u_{\rm c}(r|M) = \delta^{\rm D}(r)$$

#### **Satellite Galaxies**

$$\langle N_{
m s}
angle_{M}=\sum_{N_{
m s}=0}^{\infty}N_{
m s}\,P(N_{
m s}|M)$$
 $\langle N_{
m s}^{2}
angle_{M}=\sum_{N_{
m s}=0}^{\infty}N_{
m s}^{2}\,P(N_{
m s}|M)$ 
 $u_{
m s}(r|M)={
m TBD}$ 

#### **Central Galaxies**

$$\langle N_{
m c} 
angle_M = \sum_{N_{
m c}=0}^1 N_{
m c} P(N_{
m c}|M) = P(N_{
m c}=1|M)$$
 $\langle N_{
m c}^2 
angle_M = \sum_{N_{
m c}=0}^1 N_{
m c}^2 P(N_{
m c}|M) = P(N_{
m c}=1|M) = \langle N_{
m c} 
angle_M$ 
 $u_{
m c}(r|M) = \delta^{
m D}(r)$ 

#### **Satellite Galaxies**

$$\langle N_{
m s}
angle_{M} = \sum_{N_{
m s}=0}^{\infty} N_{
m s} \, P(N_{
m s}|M)$$
 $\langle N_{
m s}^2
angle_{M} = \sum_{N_{
m s}=0}^{\infty} N_{
m s}^2 \, P(N_{
m s}|M)$ 
 $u_{
m s}(r|M) = {
m TBD}$ 

Calculating galaxy-galaxy correlation functions requires following halo occupation statistic ingredients:

Halo occupation distribution for centrals  $P(N_c|M)$ 

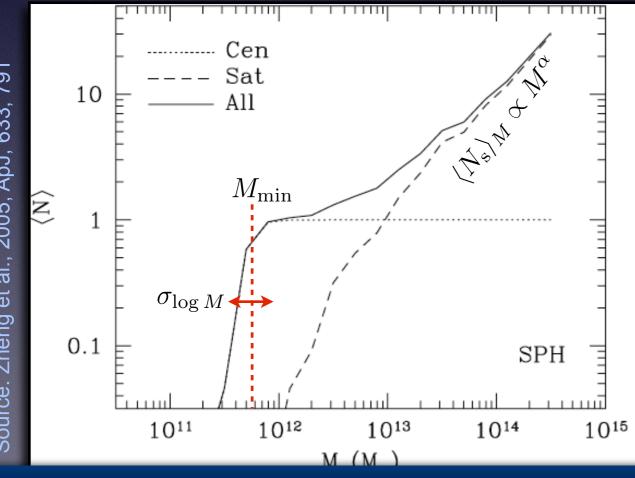

Halo occupation distribution for satellites  $P(N_{
m s}|M)$ 

Radial number density profile of satellites  $u_s(r|M)$ 

In principle, as we will see, one also requires the probability function  $P(N_c, N_s | M)$ , but it is common practice to assume that the occupation statistics of centrals and satellites are independent, i.e., that  $P(N_c, N_s | M) = P(N_c | M) \times P(N_s | M)$ 

Consider a luminosity threshold sample; all galaxies brighter than some threshold luminosity. The halo occupation statistics for such a sample are typically parameterized as follows:

$$\langle N_{\rm c} \rangle_M = rac{1}{2} \left[ 1 + \operatorname{erf} \left( rac{\log M - \log M_{\min}}{\sigma_{\log M}} 
ight) \right]$$
 $\langle N_{\rm s} \rangle_M = \left\{ \begin{array}{l} \left( rac{M}{M_1} \right)^{\alpha} & \text{if } M > M_{\mathrm{cut}} \\ 0 & \text{if } M < M_{\mathrm{cut}} \end{array} \right.$ 

 $M_{\min}$  = characteristic minimum mass of haloes that host centrals above luminosity threshold

 $\sigma_{\log M}$  = characteristic transition width due to scatter in L-M relation of centrals

 $M_{\rm cut}$  = cut-off mass below which you have zero satellites above luminosity threshold

 $M_1$  = normalization of satellite occupation numbers

 $\alpha$  = slope of satellite occupation numbers

This particular HOD model, which is fairly popular in the literature, requires 5 parameters  $(M_{\min}, M_1, M_{\text{cut}}, \sigma_{\log M}, \alpha)$  to characterize the occupation statistics of a given luminosity threshold sample, and is (partially) motivated by the occupation statistics in hydro simulations of galaxy formation...

Increasing the slope  $\alpha = d \log \langle N_s \rangle / d \log M$  boosts the 1-halo term of the correlation function. It also boosts the 2-halo term, but to a lesser extent.

The latter arises because a larger value of  $\alpha$  implies that satellites, on average, reside in more massive haloes, which are more strongly biased.

The 1-halo term scales with satellite occupation numbers as  $\langle N_{\rm s} \rangle_M^2$  while the 2-halo term scales as  $\langle N_{\rm s} \rangle_M$ . This means that the relative clustering strengths in the 1-halo and 2-halo regimes constrains the satellite fractions.

An alternative parameterization, which has the advantage that it describes the occupation statistics for any luminosity sample (not only threshold samples), is the conditional luminosity function.

$$\Phi(L|M) = \Phi_{c}(L|M) + \Phi_{s}(L|M)$$

The CLF describes the average number of galaxies of luminosity L that reside in a dark matter halo of mass M.

$$\Phi(L) = \int_0^\infty \Phi(L|M) \, n(M) \, dM$$

CLF is the direct link between the halo mass function and the galaxy luminosity function.

$$\langle L \rangle_M = \int_0^\infty \Phi(L|M) L \, \mathrm{d}L$$

CLF describes link between luminosity and mass

$$\langle N_{\mathbf{x}} \rangle_M = \int_{L_1}^{L_2} \Phi_{\mathbf{x}}(L|M) \, \mathrm{d}L$$

CLF describes first moments of halo occupation statistics of any luminosity sample

## The Conditional Luminosity Function

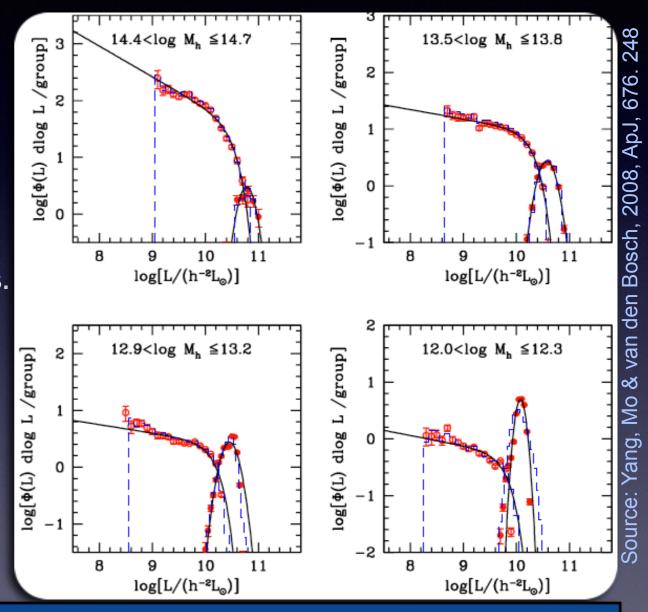

The CLF can be obtained from galaxy group catalogues. Yang, Mo & van den Bosch (2008) have shown that the CLF is well parameterized using the following functional form:

$$\Phi_{c}(L|M)dL = \frac{1}{\sqrt{2\pi}\sigma_{c}} \exp\left[-\left(\frac{\ln(L/L_{c})}{\sqrt{2}\sigma_{c}}\right)^{2}\right] \frac{dL}{L}$$

$$\Phi_{s}(L|M)dL = \frac{\phi_{s}}{L_{s}} \left(\frac{L}{L_{s}}\right)^{\alpha_{s}} \exp\left[-(L/L_{s})^{2}\right] dL$$

Note:  $\{L_{\rm c}, L_{\rm s}, \sigma_{\rm c}, \phi_{\rm s}, \alpha_{\rm s}\}$  all depend on halo mass. These dependencies are typically parameterized using ~10 free parameters.

Free parameters are constrained by the data, which can be galaxy group catalogs, galaxy clustering, galaxy-galaxy lensing, satellite kinematics, etc...

The CLFs inferred from a SDSS galaxy group catalog. Symbols are data, while the solid, black line is best-fit using the CLF parameterization indicated above...

The 1-halo term of the galaxy-galaxy correlation function requires the second moment

$$\langle N(N-1)\rangle_{M} = \langle N_{c}^{2}\rangle_{M} + 2\langle N_{c}N_{s}\rangle_{M} + \langle N_{s}^{2}\rangle_{M} - \langle N_{c}\rangle_{M} - \langle N_{s}\rangle_{M}$$
$$= \langle N_{s}(N_{s}-1)\rangle_{M} + 2\langle N_{c}\rangle_{M} \langle N_{s}\rangle_{M}$$

where we assumed that occupation statistics of centrals and satellites are independent

Thus, we need to specify the second moment of the satellite occupation distribution:

$$\langle N_{\rm s}(N_{\rm s}-1)\rangle_M = \sum_{N_{\rm s}=0}^{\infty} N_{\rm s}(N_{\rm s}-1) P(N_{\rm s}|M) \equiv \beta(M) \langle N_{\rm s}\rangle^2$$

where we have introduced the function  $\beta(M)$ 

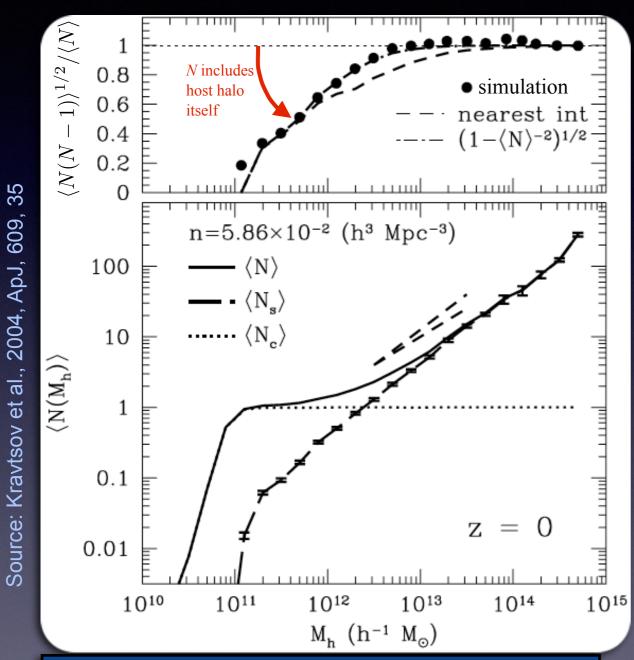

If the occupation statistics of satellite galaxies follow Poisson statistics, i.e.,

$$P(N_{
m s}|M)=rac{\lambda^{N_{
m s}}\,e^{-\lambda}}{N_{
m s}!} \qquad ext{with} \qquad \lambda=\langle N_{
m s}
angle_M$$

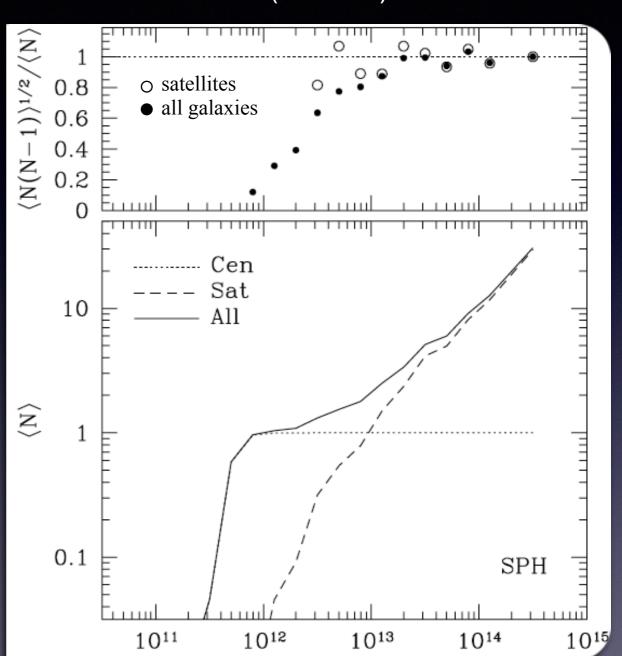

then  $\beta(M) = 1$ . Distributions with  $\beta > 1$  ( $\beta < 1$ ) are broader (narrower) than Poisson.

The second moment of the halo occupation statistics is completely described by  $\beta(M)$ 

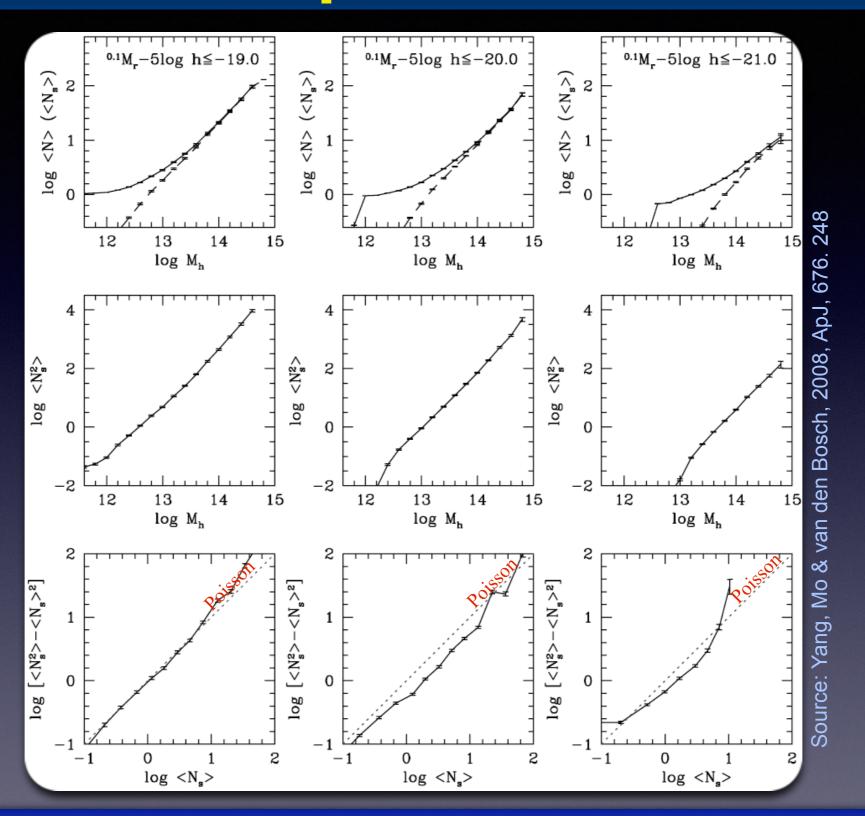

It is common practice to assume that satellites obey Poisson statistics. This is motivated by finding that dark matter subhaloes have occupation statistics that are (close to) Poissonian

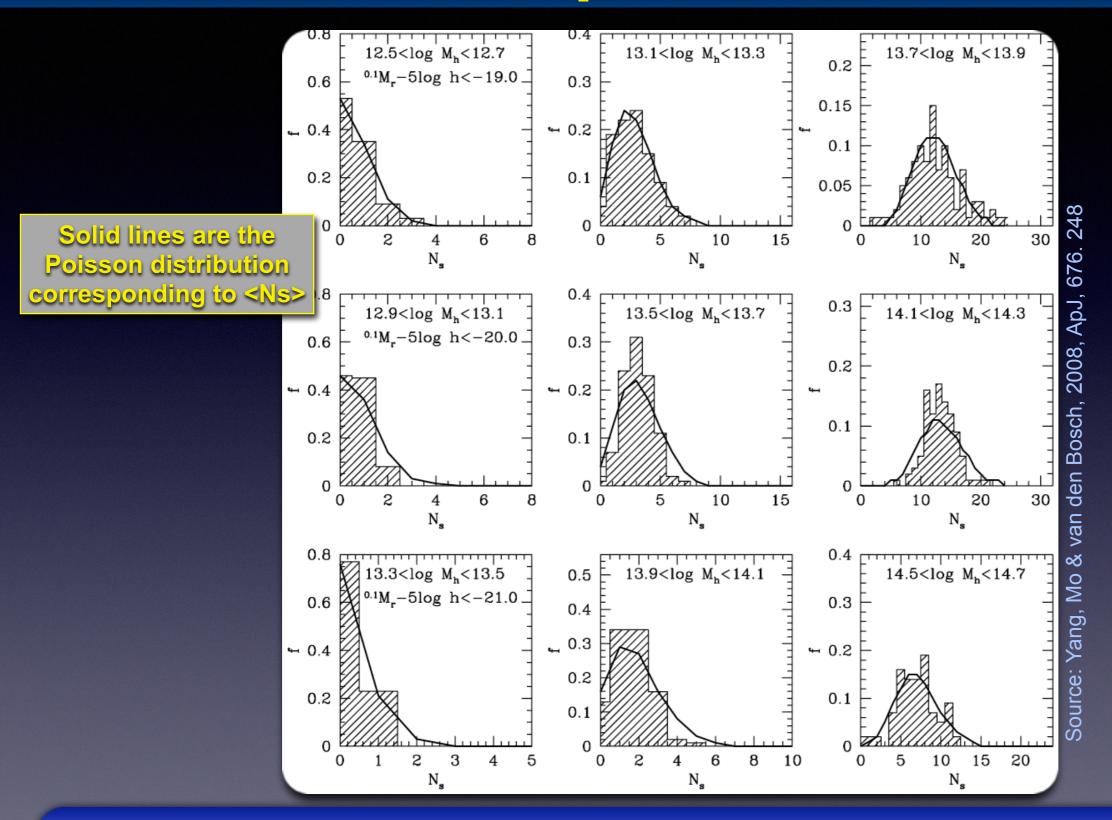

Occupation statistics of dark matter subhaloes in numerical (dark-matter-only) simulations. Subhaloes follow Poisson statistics...

Occupation statistics of simulated galaxies in hydrodynamical SPH simulations. Satellite galaxies follow Poisson statistics...

Even real data shows that the occupation statistics of satellites are (close to) Poissonian.

Even real data shows that the occupation statistics of satellites are (close to) Poissonian.

## Radial Number Density Profile of Satellites

The radial number density profile of satellite galaxies is typically modelled as a

`generalized NFW profile':

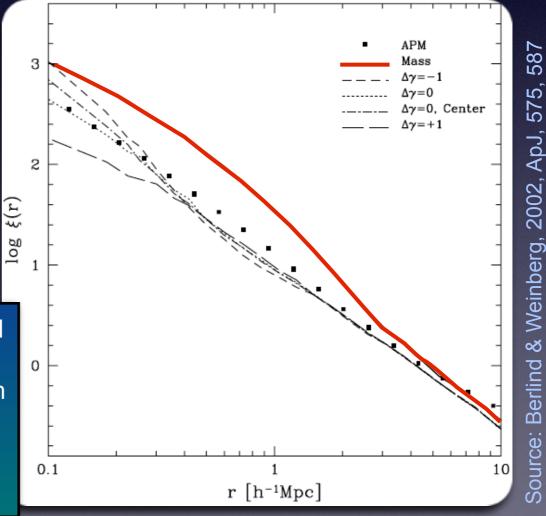

$$u_{\mathrm{s}}(r|M) \propto \left(\frac{r}{\mathcal{R} r_{\mathrm{s}}}\right)^{-\gamma} \left[1 + \frac{r}{\mathcal{R} r_{\mathrm{s}}}\right]^{\gamma - 3}$$

Here  $\gamma$  is a parameter that controls the central cusp slope, and  $\mathcal{R}=c_{\rm sat}/c_{\rm dm}$  sets the ratio between the concentration parameter of the satellites and that of the dark matter. For  $\gamma=\mathcal{R}=1$  satellites are an unbiased tracer of the mass distribution (within

individual haloes)

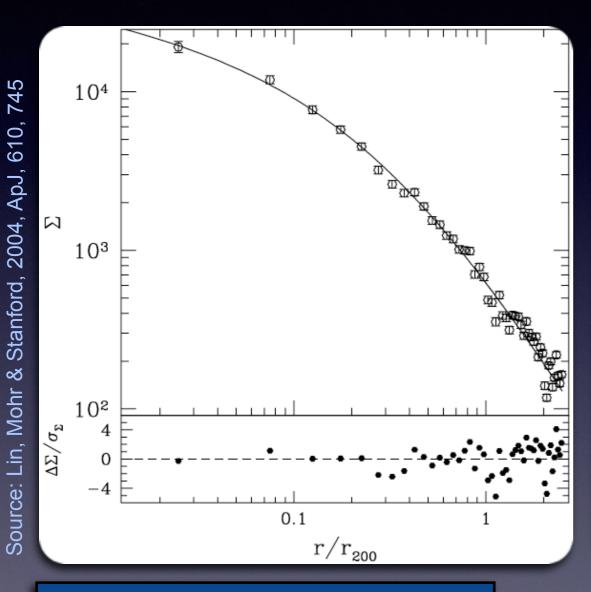

The radial number density profile of satellites controls the clustering on small scales (only has significant effect on 1-halo term).

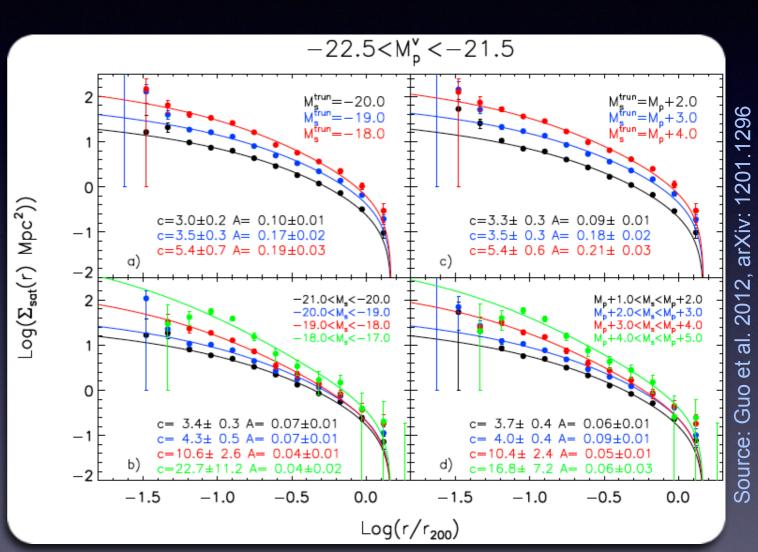

The two-point correlation function of galaxies, calculated using the halo model. Solid dots are data from the APM catalogue. The solid line is the model's matter correlation function, and the other lines are galaxy correlation functions in which the number density profile of satellite galaxies is varied.

## Radial Number Density Profile of Satellites

The radial number density profile of satellite galaxies can be constrained using the clustering data itself, or by directly measuring the (projected) profiles of satellite galaxies in groups/clusters, or around isolated centrals...

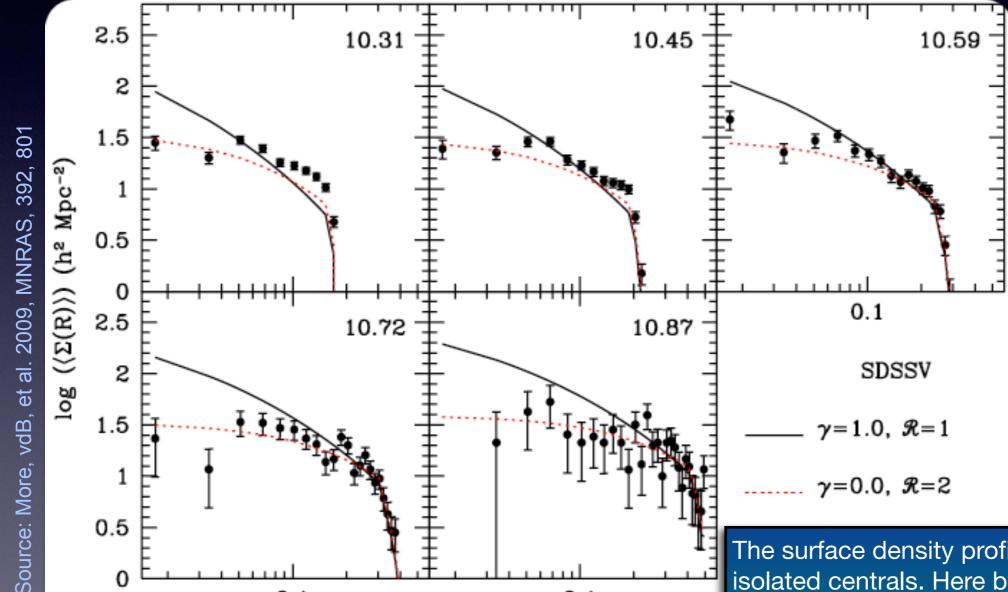

The surface density profile of satellite galaxies in clusters. Solid line is the best-fit NFW profile.

The surface density profiles of satellite galaxies around isolated centrals in the SDSS. Satellites are identified in photometric catalogue using statistical background subtraction. Lines are best-fit NFW profiles.

#### Radial Number Density Profile of Satellites

Although several studies have suggested that satellite galaxies follow a radial number density profile that is well fitted by NFW profile, others find that  $u_s(r|M)$  has a core and is less centrally concentrated than the dark matter.

This is consistent with distribution of subhaloes in dark-matter-only simulations....

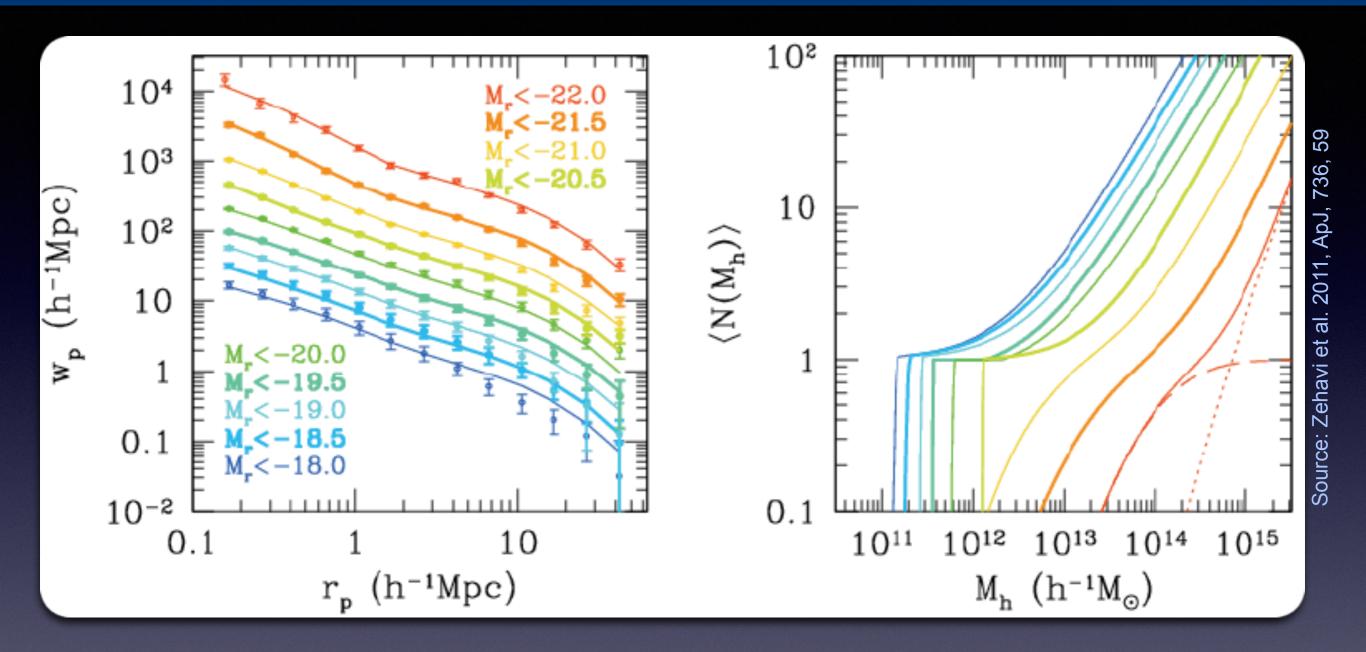

0.1

R (h-1Mpc)

The surface density profile of satellite galaxies around isolated centrals. Here both centrals & satellites are obtained from the spectroscopic SDSS. Note that cored profiles are better fit than NFW profile.

New physics beyond the "vanilla" LCDM cosmology or systematic errors?

## Summary: key words & important facts

#### Key words

Halo model halo exclusion galaxy-galaxy lensing

1-halo & 2-halo terms
Halo Occupation Distribution (HOD)
Conditional Luminosity Function (CLF)

- The Halo model is an analytical model that describes dark matter density distribution in terms of its halo building blocks, under ansatz that all dark matter is partitioned over haloes.
- In combination with a halo occupation model (HOD or CLF), the halo model can be used to compute galaxy-galaxy correlation function and galaxy-matter cross-correlation function. The latter is related to the excess surface density measured with galaxy-galaxy lensing.
- HOD is mainly used to model clustering of luminosity threshold samples.
   CLF can be used to model clustering of galaxies of any luminosity (bin).
- It is common to assume that satellite galaxies obey Poisson statistics, such that  $\langle N_s(N_s-1)|M\rangle = \langle N_s\rangle^2$ , and only the first moment of  $P(N_s|M)$  is required. This is not exact and may cause significant errors in the predicted clustering.

## Summary: key equations & expressions

halo model 
$$P^{1\mathrm{h}}(k) = \frac{1}{\overline{\rho}^2} \int \mathrm{d}M \, M^2 \, n(M) \, |\tilde{u}(k|M)|^2$$
 
$$P(k) = P^{1\mathrm{h}}(k) + P^{2\mathrm{h}}(k)$$

$$P^{2h}(k) = P^{lin}(k) \left[ \frac{1}{\overline{\rho}} \int dM M b(M) n(M) \tilde{u}(k|M) \right]^2$$

Galaxy-Galaxy lensing: tangential shear, excess surface density and galaxy-matter cross correlation

$$\gamma_{\rm t}(R)\Sigma_{\rm crit} = \Delta\Sigma(R) = \bar{\Sigma}(\langle R) - \Sigma(R)$$

$$\Sigma(R) = \bar{\rho} \int_{0}^{D_{\rm s}} [1 + \xi_{\rm g,dm}(r)] \,\mathrm{d}\chi$$

CLF: the link between light and mass

$$\Phi(L) = \int_0^\infty \Phi(L|M) \, n(M) \, dM \qquad \langle L \rangle_M = \int_0^\infty \Phi(L|M) \, L \, dL \qquad \langle N_{\mathbf{x}} \rangle_M = \int_{L_1}^{L_2} \Phi_{\mathbf{x}}(L|M) \, dL$$

Characteristic examples of CLF and HOD for both centrals and satellites

$$\Phi_{c}(L|M)dL = \frac{1}{\sqrt{2\pi}\sigma_{c}} \exp\left[-\left(\frac{\ln(L/L_{c})}{\sqrt{2}\sigma_{c}}\right)^{2}\right] \frac{dL}{L} \qquad \langle N_{c}\rangle_{M} = \frac{1}{2} \left[1 + \operatorname{erf}\left(\frac{\log M - \log M_{\min}}{\sigma_{\log M}}\right)\right]$$

$$\Phi_{s}(L|M)dL = \frac{\phi_{s}}{L_{s}} \left(\frac{L}{L_{s}}\right)^{\alpha_{s}} \exp\left[-(L/L_{s})^{2}\right] dL \qquad \langle N_{s}\rangle_{M} = \begin{cases} \left(\frac{M}{M_{1}}\right)^{\alpha} & \text{if } M > M_{\text{cut}} \\ 0 & \text{if } M < M_{\text{cut}} \end{cases}$$
