

Probing Dark Matter Halos with Satellite Kinematics & Weak Lensing

Frank C. van den Bosch (MPIA)

Collaborators: Surhud More, Marcello Cacciato

Galaxy Formation in a Nutshell

- Perturbations grow due to gravitational instability and collapse to produce (virialized) dark matter halos
- Baryons cool, accumulate at center, and form stars \Rightarrow galaxy
- Dark matter halos merge, causing hierarchical growth
- Halo mergers create satellite galaxies that orbit halo

Halo Mass Functions and Occupation Numbers

Using the halo mass inferred from clustering strength
the corresponding number density from the halo mass function,
and the observed number density of the galaxies,
one obtains the **average occupation numbers**

The Conditional Luminosity Function

In order to parameterize the Halo Occupation Statistics we introduce the **Conditional Luminosity Function** (CLF), $\Phi(L|M)$, which is the direct link between the halo mass function $n(M)$ and the galaxy luminosity function $\Phi(L)$:

$$\Phi(L) = \int_0^\infty \Phi(L|M) n(M) dM$$

The CLF contains a wealth of information, such as:

- The average relation between **light** and **mass**:

$$\langle L \rangle(M) = \int_0^\infty \Phi(L|M) L dL$$

- The occupation numbers of galaxies:

$$\langle N \rangle(M) = \int_{L_{\min}}^\infty \Phi(L|M) dL$$

We constrain the **CLF** using the luminosity function, $\Phi(L)$, and the correlation lengths as function of luminosity, $r_0(L)$, from **SDSS**

On average only ~ 2 satellites per central \rightarrow **stacking**

Unless $P(M|L_c)$ is a Dirac delta function, stacking means combining halos of different masses

Consequently, one has to distinguish two different weighting schemes:

Satellite Weighting: each satellite receives weight of one

$$\sigma_{sw}^2 = \frac{\int P(M|L_c) \langle N_{sat} \rangle_M \sigma_{sat}^2(M) dM}{\int P(M|L_c) \langle N_{sat} \rangle_M dM}$$

Host Weighting: each host receives weight of one

$$\sigma_{hw}^2 = \frac{\int P(M|L_c) \sigma_{sat}^2(M) dM}{\int P(M|L_c) dM}$$

Galaxy-Galaxy Lensing

The mass associated with galaxies lenses background galaxies

Lensing causes correlated ellipticities, the **tangential shear**, γ_t , which is related to the **excess surface density**, $\Delta\Sigma$, according to

$$\gamma_t(R) \Sigma_{\text{crit}} = \Delta\Sigma(R) = \bar{\Sigma}(< R) - \Sigma(R)$$

$\Sigma(R)$ is line-of-sight projection of **galaxy-matter cross correlation**:

$$\Sigma(R) = \bar{\rho} \int_0^{D_S} [1 + \xi_{g, \text{dm}}(r)] d\chi$$

The Measurements

- Number of background sources per lens is limited.
- Measuring γ_t with sufficient S/N requires **stacking** of many lenses
- $\Delta\Sigma(R|L_1, L_2)$ has been measured using the **SDSS** by Mandelbaum et al. (2005) for different bins in lens luminosity

• How to interpret the signal?

• Comparison with CLF

Predictions

• Cosmological Constraints

Conclusions

Extra Material

How to interpret the signal?

Because of **stacking** the lensing signal is difficult to interpret

$$\Delta\Sigma(R|L) = [1 - f_{\text{sat}}(L)]\Delta\Sigma_{\text{cen}}(R|L) + f_{\text{sat}}(L)\Delta\Sigma_{\text{sat}}(R|L)$$

$$\Delta\Sigma_{\text{cen}}(R|L) = \int P_{\text{cen}}(M|L) \Delta\Sigma_{\text{cen}}(R|M)dM$$

$$\Delta\Sigma_{\text{sat}}(R|L) = \int P_{\text{sat}}(M|L) \Delta\Sigma_{\text{sat}}(R|M)dM$$

$P_{\text{cen}}(M|L)$ and $P_{\text{sat}}(M|L)$ can be computed from $\Phi_{\text{cen}}(L|M)$ and $\Phi_{\text{sat}}(L|M)$ and so can $f_{\text{sat}}(L)$

Using $\Phi(L|M)$ constrained from **clustering data**, we can predict the **lensing signal** $\Delta\Sigma(R|L_1, L_2)$

Conclusions

Three methods to statistically constrain $P(M|L)$

Clustering

Satellite Kinematics

Galaxy-Galaxy Lensing

- Requires selection of **centrals** and **satellites** from redshift surveys
- Requires **stacking** and is therefore sensitive to **scatter** in $P(M|L)$
- Using **satellite weighting** and **host weighting** simultaneously constrains both mean and scatter of $P(M|L)$
- Scatter in $P(M|L)$ increases strongly with increasing L
- Scatter in $P(L|M)$ is independent of halo mass with $\sigma_{\log L} = 0.16 \pm 0.04$
- **Stochasticity** in galaxy formation well constrained and consistent with model predictions
- Even with large redshift surveys such as SDSS, statistics are limited
- Data not sufficient to discriminate between **WMAP1** and **WMAP3**

Introduction

Satellite Kinematics

Galaxy-Galaxy Lensing

Conclusions

● Conclusions

● Conclusions

● Conclusions

Extra Material

Conclusions

Three methods to statistically constrain $P(M|L)$

Clustering

Satellite Kinematics

Galaxy-Galaxy Lensing

- Lensing probes masses directly
- Requires **stacking** and is therefore sensitive to **scatter** in $P(M|L)$
- Very sensitive to satellite fractions $f_{\text{sat}}(L)$
- Most easily interpreted with use of CLF $\Phi(L|M)$
- Combination of **lensing** and **clustering** holds potential to tightly constrain cosmological parameters
- This method is complementary to cosmological constraints from **galaxy power spectrum**, which only probes linear scales
- Current data strongly favors **WMAP3** over **WMAP1** cosmology
