

# Predicting ‘analytically’ stripped and re-accreted mass fraction

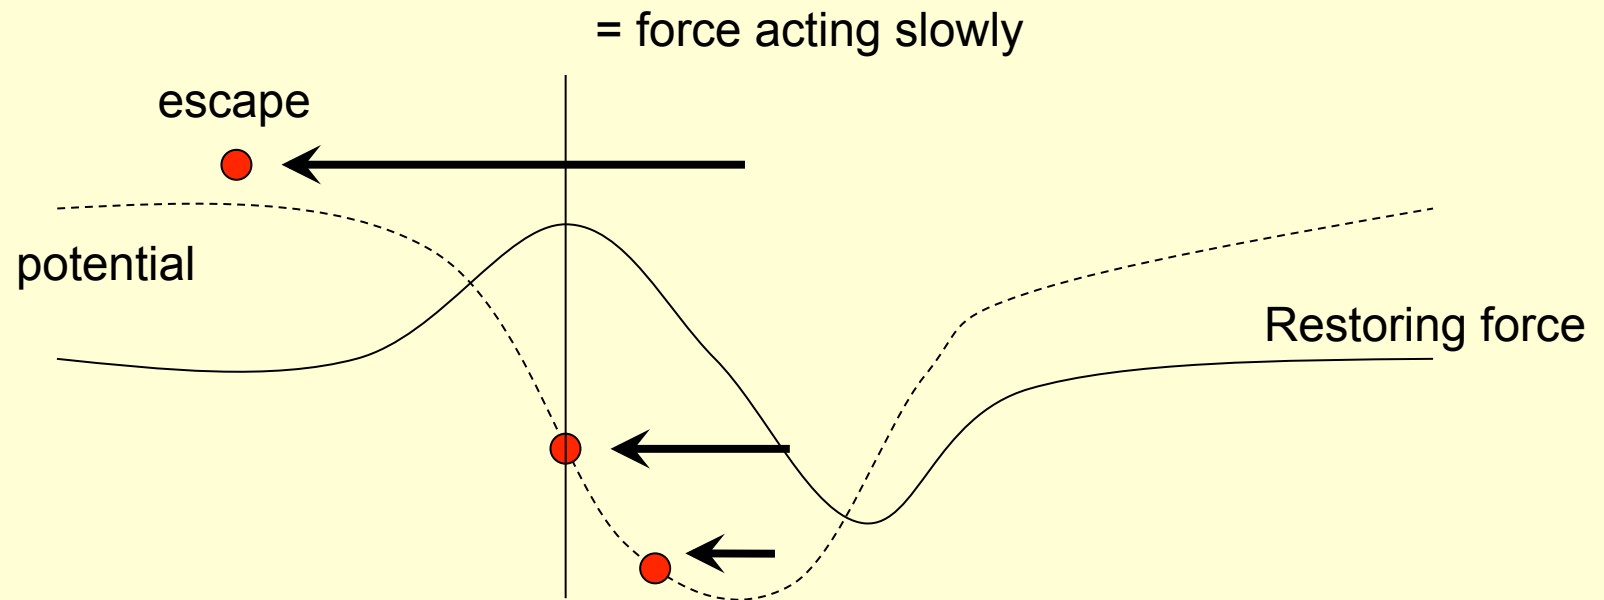

Observatoire astronomique  
de Strasbourg

Joachim Köppen

# A gas parcel in the galactic disk

# Gunn & Gott criterion

# What happens after a short force pulse?

# Taking RPS as a collision

- Momentum balance

$$\Sigma_{\text{ISM}} * v_{\text{AFTER}} = \Sigma_{\text{ICM}} * v_{\text{ICM}}$$

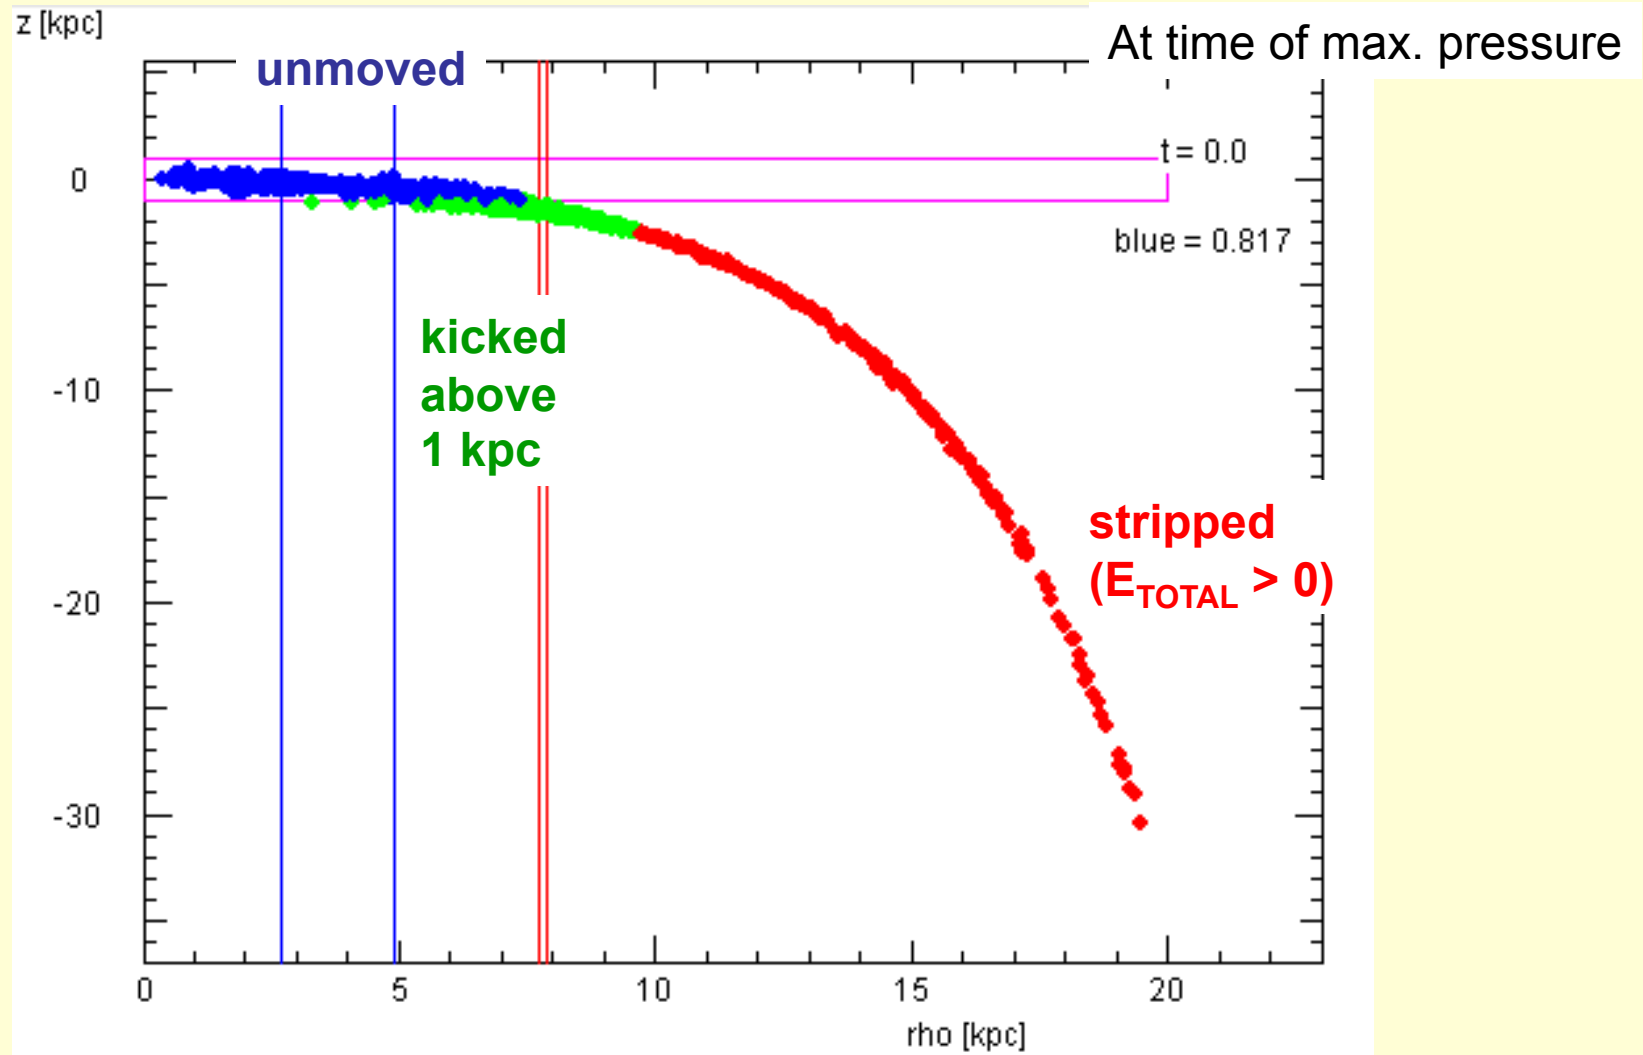

- Stripping if

$$v_{\text{AFTER}} > v_{\text{ESC}}$$

- Works well to explain stripped mass fractions in Pavel's SPH models

How to predict the re-accretable  
fraction?

# Simulations with test particle models

# Remember the ballistic galvanometer?

- If an undamped harmonic oscillator is kicked by a pulse shorter than its natural period, it will oscillate with an amplitude which is proportional to the time-integrated force i.e. the momentum transferred to it.

NB: The amplitude is independent of the form of the pulse.

# Period of vertical oscillations

period of vertical oscillations [Myr]

Pavel's  
« standard » run

10 Myr

# Let's apply it to face-on RPS

- Equation of motion

$$d(\Sigma_{ISM}v)/dt = \rho_{ICM} (v_{ICM}-v)^2 - \Sigma_{ISM} d\Phi/dz$$

- Solution: (a) during the kick ( $z = v = 0$ )

$$\Sigma_{ISM} v_{AFTER} = \rho_{ICM} v_{ICM}^2 \Delta t$$

- Solution: (b) after the kick (Force=0;  $v = v_{AFTER}$ )

$$d(\Sigma_{ISM}v)/dt = - \Sigma_{ISM} d\Phi/dz$$

→ (harmonic) oscillation with amplitude corresponding to initial kick ...

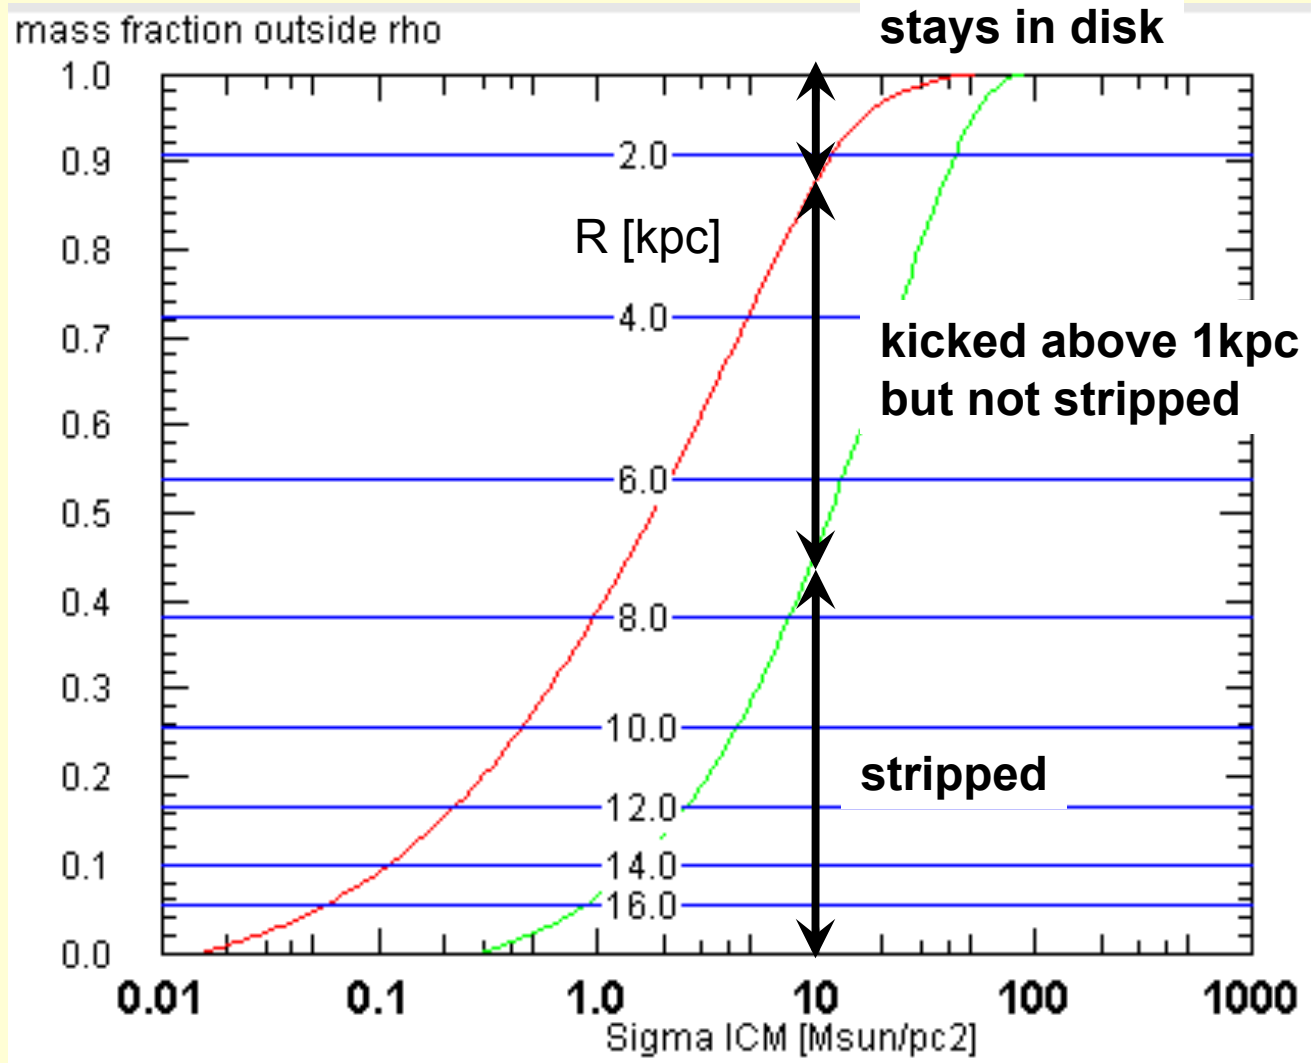

- the important parameter:

$$\rho_{ICM} v_{ICM}^2 \Delta t = v_{ICM} (\rho_{ICM} v_{ICM} \Delta t) = v_{ICM} \Sigma_{ICM}$$

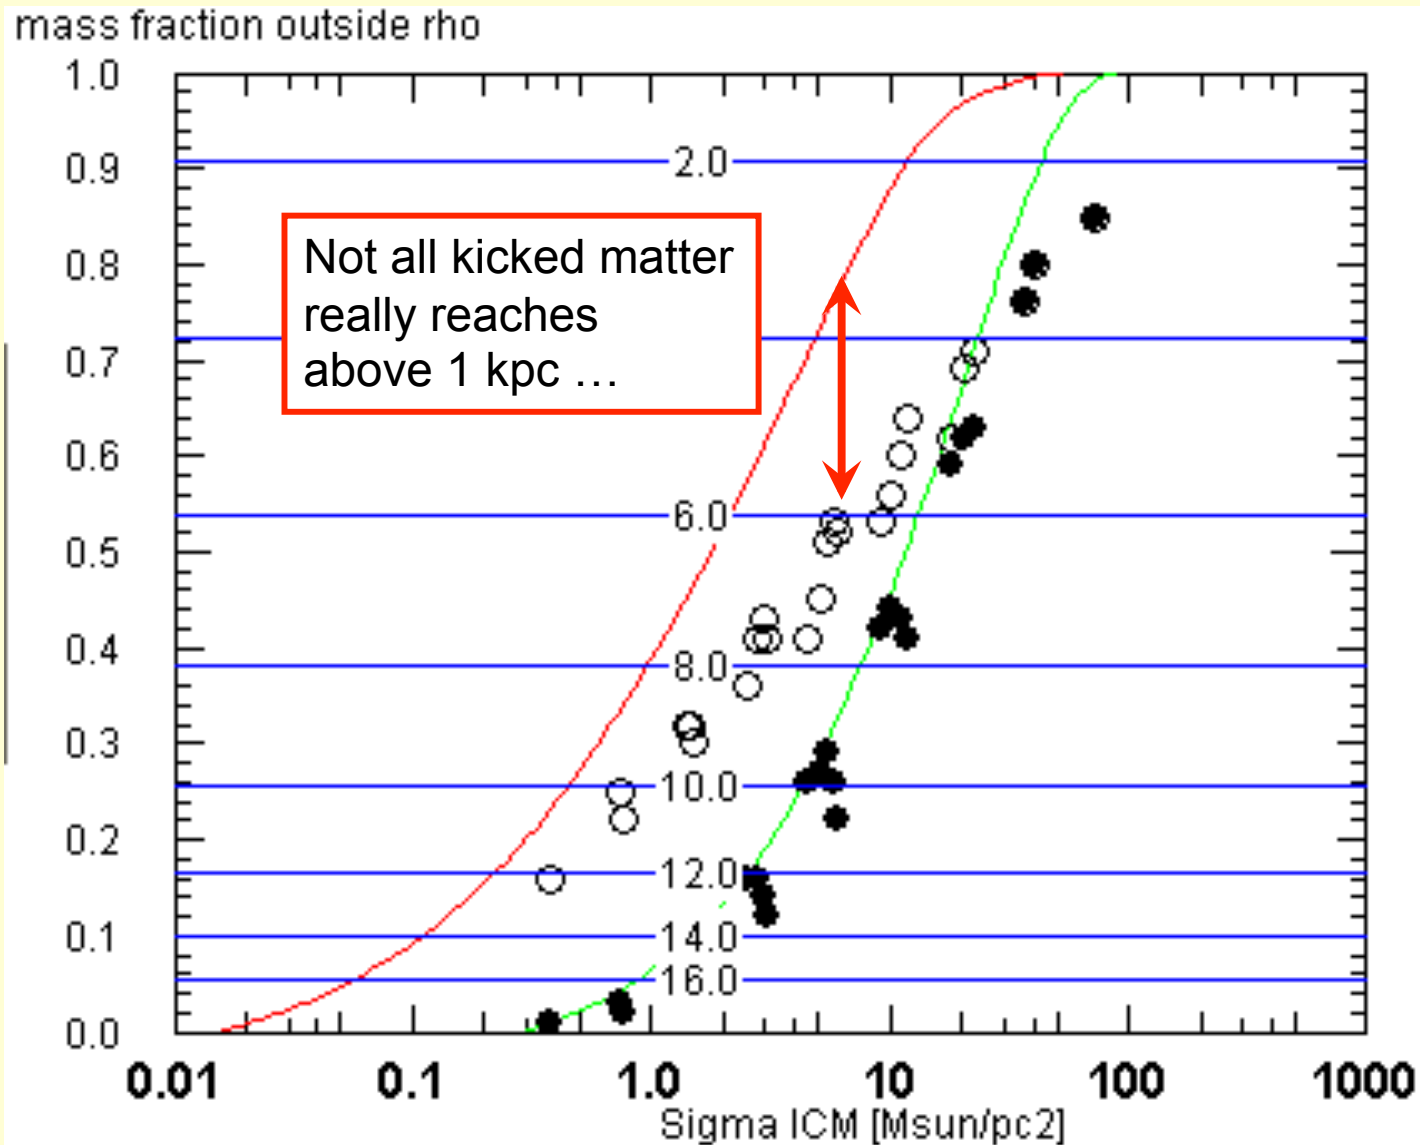

# Given the speed after the kick

- ... and the potential, we can compute how high above the disk the gas packet can move
- ... and hence we can predict which parts of the disk will be displaced by some minimum height, say 1 kpc

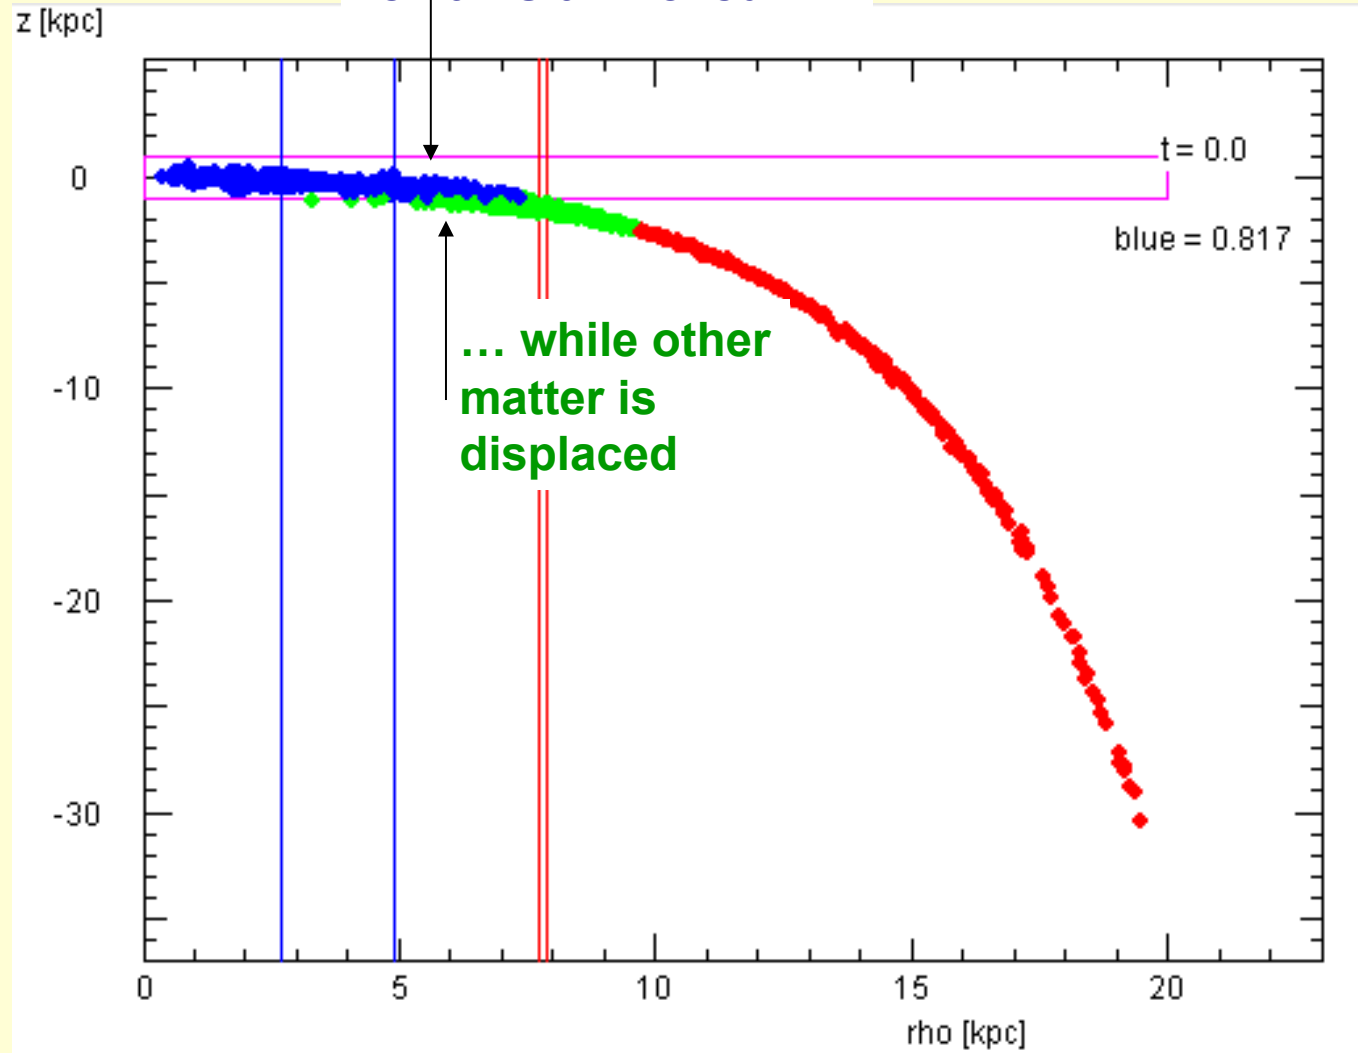

# We get

# Compare with Pavel's SPH models

Depending on the initial vertical velocity some kicked matter remains unmoved

# Summary

- Momentum transfer determines the fate of a gas parcel
- The primary parameter is the column density  $\Sigma_{\text{ICM}}$  of the accumulated ICM
- For the reaccreted fraction we can give only an upper limit
- For slow stripping, the efficiency of momentum transfer will be less!
